Abstract

Anomaly detection in the Enron Email Network.

1 Experiments

In this experiment, we use the Enron email dataset¹. It contains 614586 emails sent over the period from 6 January 1998 until 4 February 2004. During the pre-processing we remove the periods of low activity and keep the emails from 1 January 1999 until 31 July 2002 which is 1448 days of email records in total. Also, we remove email addresses that sent less than three emails over that period.

To build a graph $G = (V, E, W)$, we use email addresses as nodes V . Every node $v_i \in V$ has an attribute which is a time-varying signal that corresponds to the number of emails sent from this address during a day. We draw an edge $e_{ij} \in E$ between two nodes i and j if there is at least one email exchange between the corresponding addresses. Initial weights W are equal to 0.

In order to detect anomalies in the network activity, we apply the proposed algorithm to the Enron email network and compare our findings to the results presented in².
